

Introduction to RNA-Seq – Differential Expression

Wandrille Duchemin

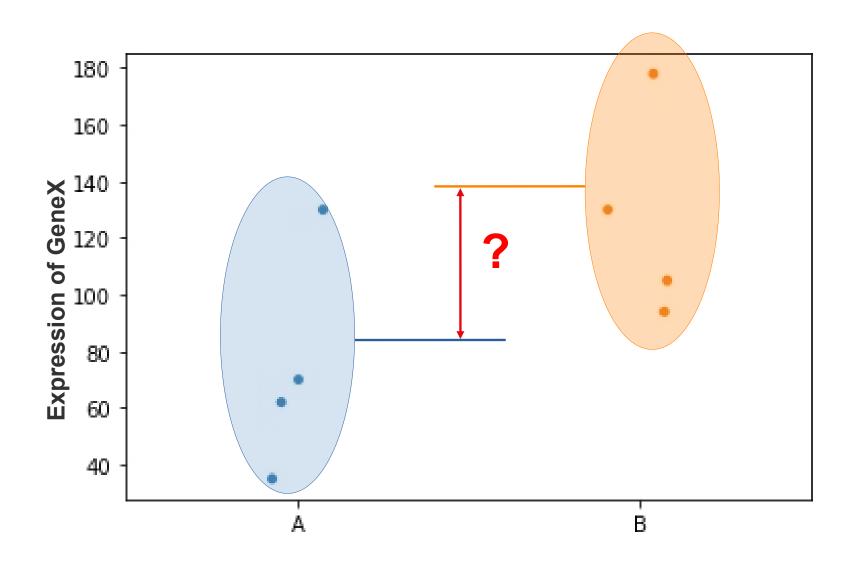

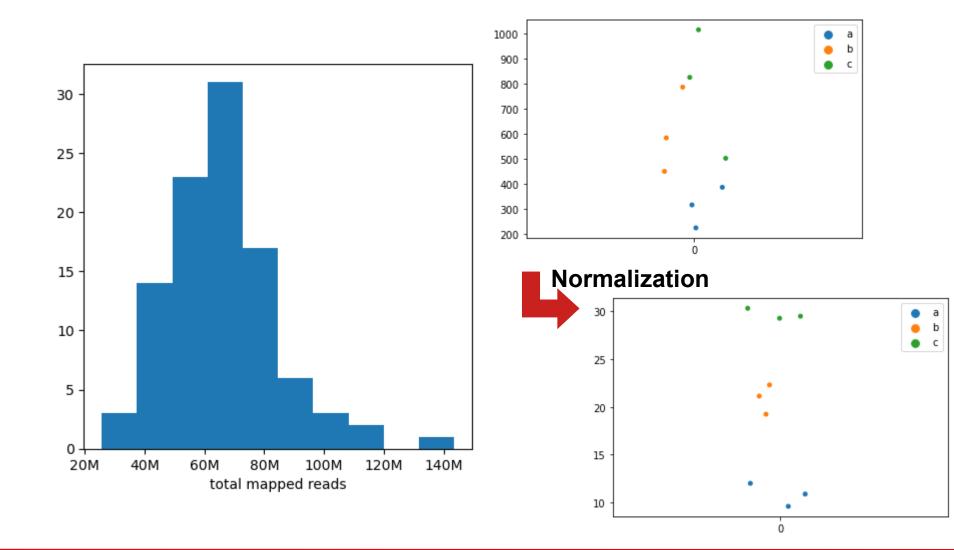

DE – the goal

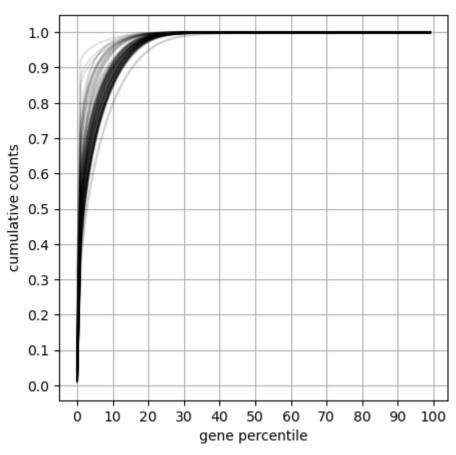

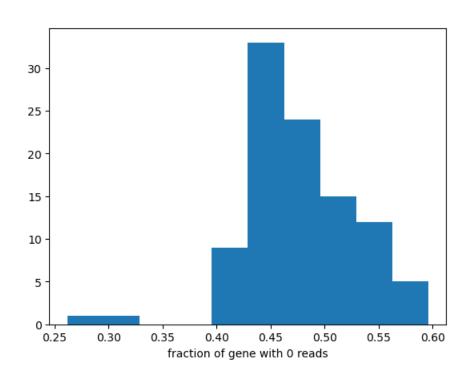

- Sequencing depth varies across libraries
- High dynamic range
- Limited number of samples
- Large number of genes

Sequencing depth varies across libraries

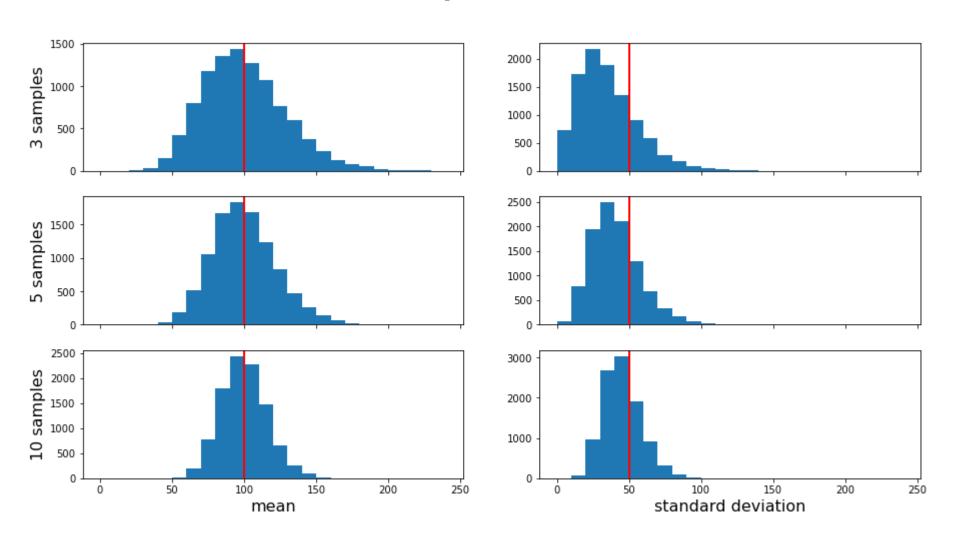

High dynamic range

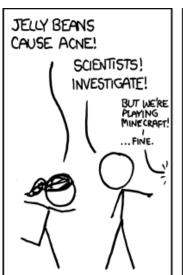

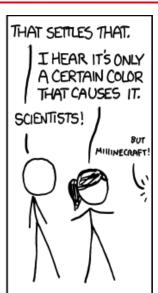

Limited number of samples

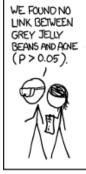

Large number of genes to test

DE – Input for Gene Differential Expression

- Counts from mapping
 - Handling of overlap? Stranding?
 - Multi-mapping reads?
 - Affected by library size
- TPM from pseudo-aligners
 - Tximport aggregates counts at the gene-level

DE – Input for Gene Differential Expression

- Counts from mapping
 - Handling of overlap? Stranding?
 - Multi-mapping reads?
 - Affected by library size
- TPM from pseudo-aligners
 - Tximport aggregates counts at the gene-level

EdgeR and DESeq2 expect raw counts

DE – digression: "naive" normalization

- CPM (Count Per Million): count / library size * 10⁶
- RPKM (Reads Per Kilobase per Million):
 - CPM / gene length (kb)

- TPM (Transcript Per Million):
 - RPK = Count / gene length (kb)
 - RPK / sum(RPK) * 10⁶

DE – "naive" normalization

- CPM (Count Per Million) : count / library size * 10⁶
- RPKM (Reads Per Kilobase per Million):
 - CPM / gene length (kb)

Sum RPKM different between samples

- TPM (Transcript Per Million):
 - RPK = Count / gene length (kb)
 - RPK / sum(RPK) * 106

Sum TPM constant between samples

DE – "naive" normalization

- CPM (Count Per Million) : count / library size * 10⁶
- RPKM (Reads Per Kilobase per Million):
 - CPM / gene length (kb)

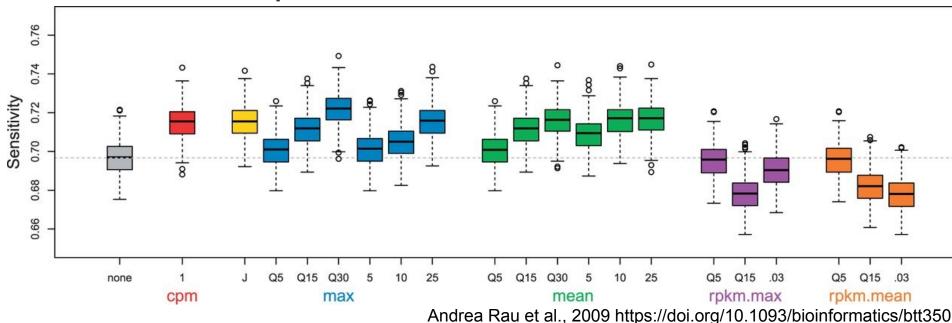

How do you compute "gene length"?

- TPM (Transcript Per Million):
 - RPK = Count / gene length (kb)
 - RPK / sum(RPK) * 10⁶

DE – Filtering low count genes

Very low counts genes :

- Very little information. No chance of DE.
- Filter: less p-value correction

EdgeR: CPM > 10/(min lib size) in at least N samples

DESeq2: mean normalized count optimizing # of DEG

DE - Normalization

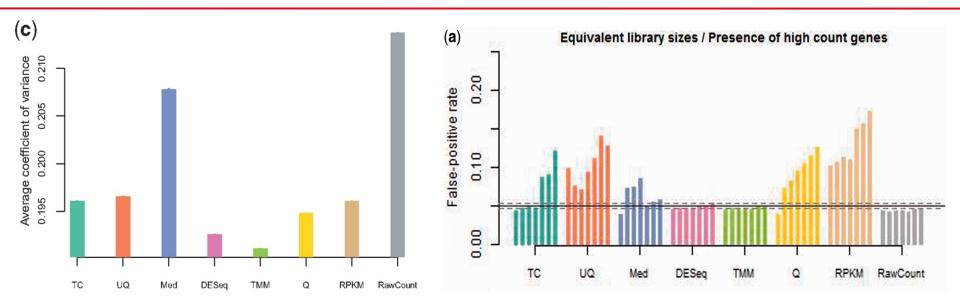

Table 3: Summary of comparison results for the seven normalization methods under consideration

Method	Distribution	Intra-Variance	Housekeeping	Clustering	False-positive rate
TC	_	+	+	_	_
UQ	++	++	+	++	_
Med	++	++	_	++	_
DES eq	++	++	++	++	++
TMM	++	++	++	++	++
Q	++	_	+	++	_
RPKM	_	+	+	_	_

A'—' indicates that the method provided unsatisfactory results for the given criterion, while a '+' and '++' indicate satisfactory and very satisfactory results for the given criterion.

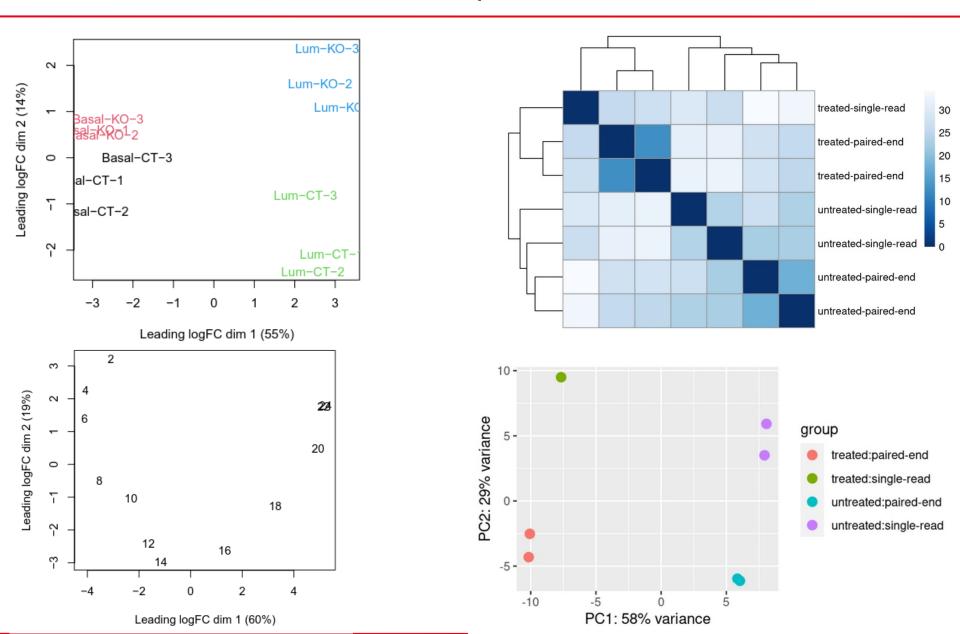

Dillies et al 2013 https://doi.org/10.1093/bib/bbs046

DE – Normalization

- EdgeR: "Trimmed Mean of M-Values" (TMM)
- DESeq2 : "Relative Log Expression" (RLE)

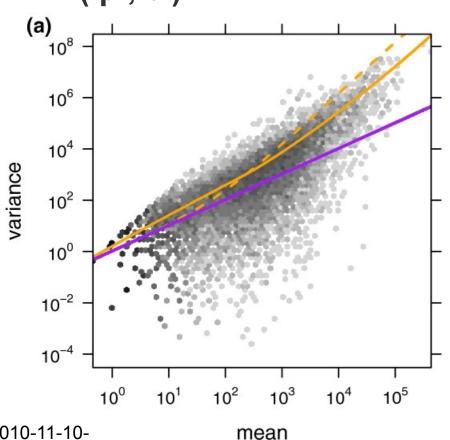

Both presume that most genes are not DE!

QC – MDS or PCA of the samples

DE – negative binomial model

- Generalized Poisson with over-dispersion
- count of a gene in a sample ~ NB(μ , θ)
 - Variance = $\mu + \theta \mu^2$
 - θ: dispersion parameter

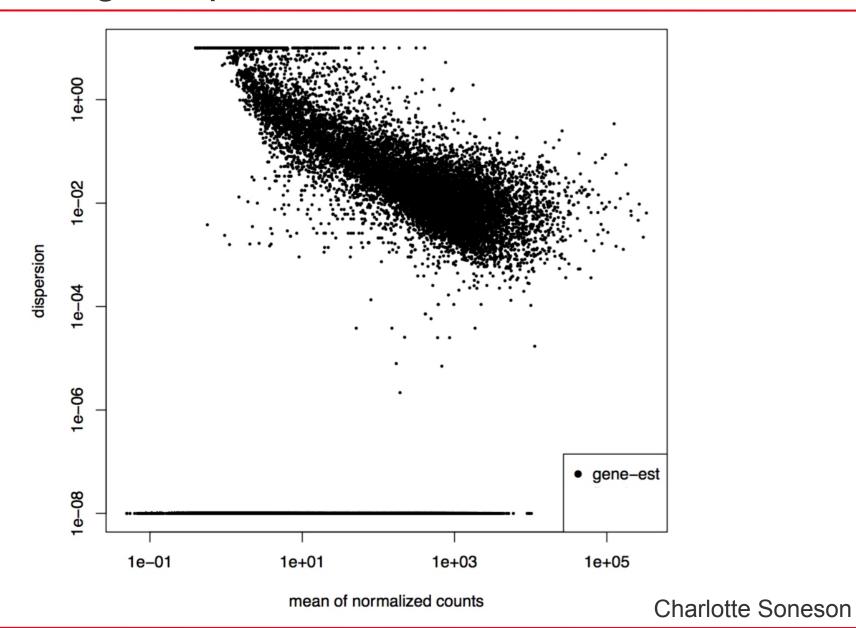

Anders, S., Huber, W. 2010 https://doi.org/10.1186/gb-2010-11-10-

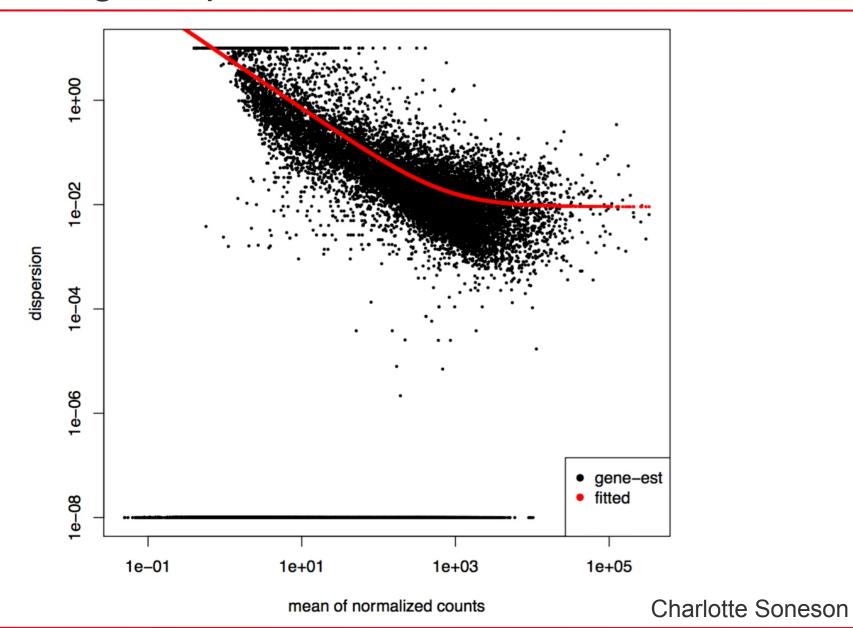

Shrinkage of dispersion estimates

- Problem: we often have few replicates
- Solution: take advantage of the large number of genes
 - shrink gene-wise estimates towards the center value observed of dispersion across genes with similar expression

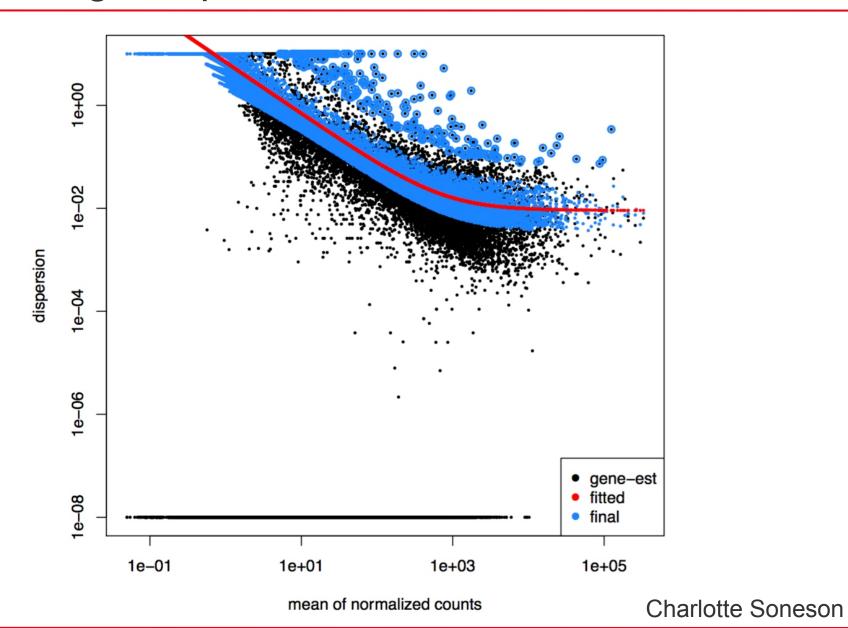

Shrinkage dispersion estimation

Shrinkage dispersion estimation

Shrinkage dispersion estimation

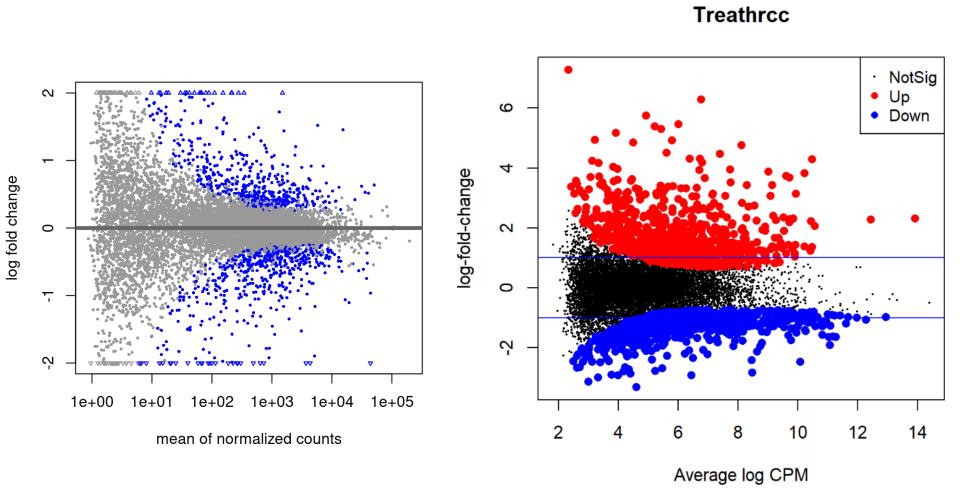

Tests for differential expression – DESeq2

- For each gene:
 - Z-score = shrunken LFC / estimate standard error
- Z-score → standard normal distribution → p-value (Wald test)
- Benjamini-Hochberg procedure to adjust p-values

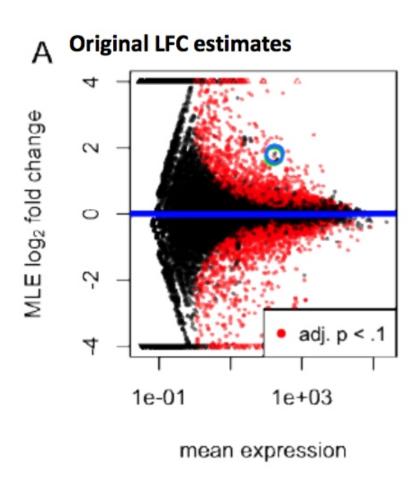

Tests for differential expression – edgeR

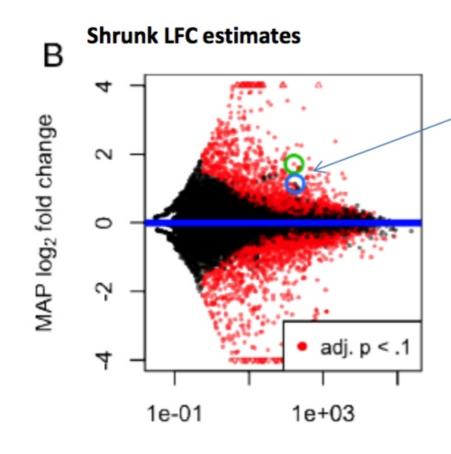

- "simple" 1 factor : exactTest() ,
 - using the computed conditional distribution for the sum of counts in a group
- Otherwise a GLM framework in used :
 - QL F-test: preferred → normally stricter error rate control
 - LRT: when "the dispersions are very large and the counts are very small, whereby some of the approximations in the QL framework seem to fail"

MA plot

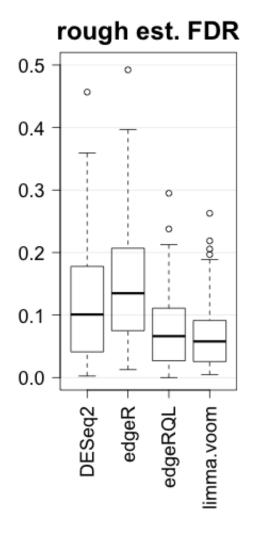

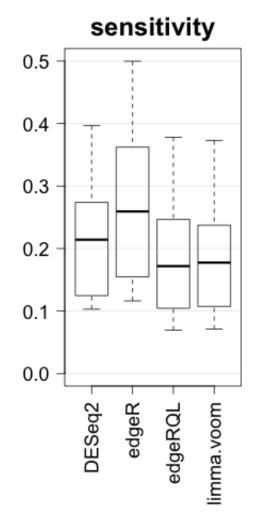

Shrinkage of log-fold change

edgeR vs DESeq2

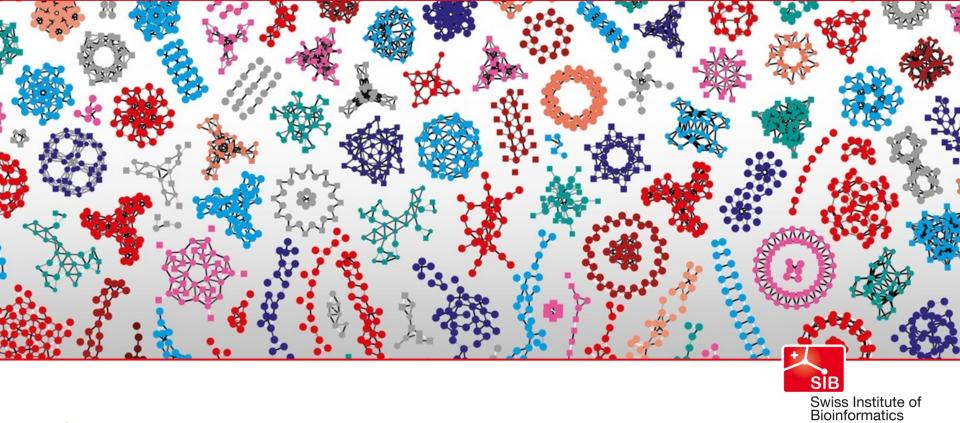

- P EdgeR-exactTest() : more sensitive
- EdgeR-QL : more conservative
- DESeq2 : tight FDR control
